FLACOURTIACEAE

Compiled by C.L. Bredenkamp

Notes: phylogenetic relationships within the Flacourtiaceae have been assessed with rbcl DNA sequences and two groups have been identified. The first group retains the family name Salicaceae as the name has nomenclatural priority, and the second group has the conserved name Achariaceae (Soltis *et al.* 2000, in *Botanical Journal of the Linnean Society* 133: 381–461; Chase *et al.* 2002, in *Kew Bulletin* 57: 141). Although Chase *et al.* (2002) have placed the Flacourtiaceae and Samydaceae in synonymy under Salicaceae and Achariaceae, the present publication retains the families Flacourtiaceae and Achariaceae for practical reasons.

Note: depending on water levels, terrestrial species sometimes grow in water, appearing aquatic. In any case, all *Utricularia* plants live under moist conditions. Most heights were obtained by measuring inflorescences, normally held erect. In aquatic forms, some part of the peduncle would be submerged.

(6) Verdcourt. 1989. *FTEA* Nymphaeaceae: 3–11.

Note: Borsch & Wiersema are currently working on a long-term global investigation of the genus *Nymphaea*. Borsch states: 'While Verdcourt's treatment of the East African *Nymphaea* is the most comprehensive one available at this time, it is based entirely on herbarium study of these plants. Such studies cannot adequately address the effects of hybridization, resulting in largely sterile intermediate plants that blur the distinctions between species if they are not recognised as such. Based on field experience studying *Nymphaea* in North and South America and Australia, I cannot accept Verdcourt's grouping of such diverse taxa as *N. caerulea*, *N. capensis* (its nomenclature problems aside), and *N. petersiana* under the largely Asiatic *N. nouchali*. I have mostly reverted to the earlier treatment of Conard in accepting these and others at species rank' (pers. comm.). Refer to http://www.victoria-adventure.org/waterlilies/family_tree.html for their proposed preliminary classification.

SCROPHULARIACEAE

Compiled by S.J. Smithies & J.A. Ready

Note: following recent molecular phylogenetic studies, there have been proposals for splitting up the polyphyletic family Scrophulariaceae into apparently monophyletic groups or clades, usually assigned a family name. One such was by Olmstead *et al.* (2001) in *American Journal of Botany* 88,2: 348–361. Here the genera were assigned to three main families: Scrophulariaceae in strict sense (including *Aptosimum*, *Hemimeris*, the Manuleae (*Zaluzianskya*), Selagineae (*Selago*) and *Verbascum*, plus families Buddlejaceae and Myoporaceae); Veronicaceae or Plantaginaceae (grouping the 'snap dragons' (*Nemesia*), *Veronica* and *Bacopa* together with *Plantago* and several other small families); and Orobanchaceae (comprising the parasites such as *Buchnera*, *Bartsia* and *Orobanche*). *Halleria* and possibly other shrub or tree genera were placed in Stilbaceae. Since many genera have not yet been examined and there are some conflicting reports, the traditional grouping of genera in the Scrophulariaceae is followed here, except that the parasites and associated genera have been placed under Orobanchaceae.

Note: there have been many changes in the taxonomy of the Scrophulariaceae, especially during the last decade. This is largely because of difficulties in finding suitable separation characters between both genera and species and superficial examinations. The Manuleae and Selagineae have been particularly difficult and many authors, prior to Hilliard, were very confused, especially Hiern (1904) and Rolfe (1901) in *Flora capensis*. Hence many of their names or synonyms are not included here. Authors often listed mixed specimens, and therefore many names have had to be cited as 'in part'. However, the other part was not always mentioned. Tracking the cited specimens has sometimes shown this information, which is of interest to those doing identifications.

Note: this genus has long needed revision, and many identifications are uncertain. All plants live under wet conditions, and many are found in places ranging from damp mud to fully submerged. Plant forms appear to be very plastic, depending on the environmental conditions—several species sometimes have small terrestrial forms and larger, somewhat different, submerged or floating ones. Because of this, Glück (1934) proposed habitat forms for many species but they have not been adopted generally.

Note: *Trapa* is in a state of flux at the moment, and is being revised by Symoens for various African floras. Owing to poorly collected material there is insufficient information on the nuts in the *FSA* region to distinguish the different varieties. Currently *T. natans* should therefore be treated in the wider sense [(3) & C.D.K. Cook, pers. comm.].
